

What the unused temporal signal would buy (D17)

The matcher blocks on names and taxonomy only: certification_date appears zero times in match_amcb_to_npi.R. This measures what a temporal comparison would add, over matches ALREADY ACCEPTED. Nothing in the published linkage is changed by it.

A. Over a third of accepted matches can never be assessed

The panel opens in 2007, so an NPI first seen in that snapshot may have enumerated earlier. Those rows are a bound, not a date, and no grace period can make them informative.

B. The default grace sits above every value in the data

lead_years = certification year - NPI first-seen year. Positive means the NPI existed BEFORE the certification, which is the suspicious direction. Negative is the normal career order: an RN enumerates before she certifies. View clipped at -25; 583 further-negative rows (to -54) fall outside it and are never flagged by a one-sided rule.

C. What a stricter grace period would actually flag

Accepted matches called implausibly early, as the grace period tightens. These are candidate false positives the name rules had no way to see -- not confirmed errors.
